pdfmole

The **pdfmole** package provides a bundle of functions designed to assist in extracting tables from PDF-files. To read-in the data either

- pdfminer,
- pdfboxr or
- tesseract can be used.

In principle, any package which returns the data in a similar format could be used. The packages **pdfminer** and **pdfboxr** can be used if the PDF-file store already the text (in most cases) if the PDF contains only images of the tables **tesseract** can be used.

1. Installation

```
# install tesseract (optional)
install.packages("tesseract")

# install pdfminer (optional)
install.packages("pdfminer")

# install pdfboxr (optional)
install.packages("pdfboxr")

# install pdfmole
install.packages("pdfmole")
```

2. Workflow

```
options(width = 100)
library("pdfboxr")
library("pdfmole")
```

The basic work flow of **pdfmole** can be divided into

- 1. read data (pdfboxr::read_chars())
- 2. align rows (align_rows(x, method, ...))
- 3. aligns columns (align_columns(x, method, ...))
- 4. group cells (group_cells(x, collapse))
- 5. transform the data into a rectangular format (mole(x, header, simplify, keep))

3. Example usage

3.1. Read data

Use **pdfboxr** (or **pdfminer**) to read the PDF-file into **R**,

```
pdf_file <- file.path(system.file("pdfs", package = "pdfmole"), "cars.pdf")
pdf <- pdfboxr::read_chars(pdf_file, pages = 1:2)
pdf

## A pdf document with 2 pages and
## metainfo text fonts
## 1 2 313 3</pre>
```

pdfboxr returns an object of class "pdf_document" which is a list containing several data.frames, the print method shows the number of rows of each data.frame. Each data.frame contains specific information about the PDF-file, for example the data.frame contains meta information about the PDF-file.

pdf\$metainfo

elements.

```
## rotation y0 x0 y1 x1 pid
## 1 0 0 0 842 595 1
## 2 0 0 0 842 595 2
```

The columns are defined as follows.

Name	Description
pid	page id
rotation	the rotation of the page
x0	the bounding box start coordinate on the x-axis
x1	the bounding box end coordinate on the x-axis
у0	the bounding box start coordinate on the y-axis
<u>y</u> 1	the bounding box end coordinate on the y-axis

The data.frame named text contains the page id, font name, font size, name of the color space, color and bounding box for each character of the PDF-file.

```
d0 <- pdf$text
d0[c("rotation", "yscale", "xscale")] <- NULL # so the output fits to the column width
head(d0)</pre>
```

```
##

                                                                              6.31
```

Based on this information we want to assign a row and column id to each row of the data.frame. This will allow us to transform character level data.frame into the typical format. Additionally we can use information like the location, font size or font type to filter out specific characters / blocks / rows.

3.2 Align blocks (optional)

The block information is assigned by **pdfminer** and signals which characters belong to the same text block. The function **group_blocks** can be use to paste together all the characters belonging to the same block. **pdfmoler** provides no block information therefore we skip this part.

```
d <- group_blocks(d0)
head(d, 3)</pre>
```

3.3 Align rows

The function align_rows(x, method, ...) currently implements three methods "exact_match", "hclust" and "fixed_width".

```
d <- align_rows(d0)
head(d, 30)</pre>
```

```
x0

            r BAAAA+LiberationSans
                                       10 298.79 769.12 302.12 774.7
                                                                       3.33
                                                                              5.58
                                                                                      1
```

3.5 Filter (optional)

```
d <- d[grep("Courier", d$font),]</pre>
```

3.6 Group cells

```
d <- group_cells(d)</pre>
head(d, 3)
      pid row col
##
                     text
## 1
            2
        1
                 2 speed
            2
## 2
                 3
        1
                     dist
## 3
        1
             4
```

3.7 Transform into a rectangular (dense) format

After the grouping the data is available similar to a simple triplet sparse matrix format (sometimes called coordinate format). To obtain the usual (dense) data.frame / matrix format the function mole() can be used.

```
x <- mole(d, header = TRUE, simplify = TRUE)
x</pre>
```

```
## X1
         speed

         25
                 85
## 50
```

The function mole() returns an object of class mole,

```
str(x)
## List of 3
## $ X1 : int [1:50] 1 2 3 4 5 6 7 8 9 10 ...
```

```
## $ speed: int [1:50] 4 4 7 7 8 9 10 10 10 11 ...
## $ dist : int [1:50] 2 10 4 22 16 10 18 26 34 17 ...
## - attr(*, "class")= chr "mole"
```

which can be coerced to either data.frame

head(as.data.frame(x))

```
##
  X1 speed dist
## 1 1
         4
             2
## 2 2
            10
## 3 3
         7
             4
## 4 4
         7
            22
## 5 5
         8 16
## 6 6
         9 10
```

or matrix.

head(as.matrix(x))

```
##
      X1 speed dist
## [1,] 1
            4
                2
